Reaction	Note: the alkene is drawn in perspective. Imagine it lying flat on a table - the H is coming toward you, that's why it's drawn as a "wedge"	"Regiochemistry"	Additions to	Alkenes "Master Organic Chemistry" masterorganicchemistry.com	may provide a	eet is not meant to be comprehensive. Your course additional material, or may not cover some of the wn here. Your course instructor is the final authority.
Hydroboration	$\begin{array}{c} R, \ R \\ R \\ \hline H \\ H_2 $	Anti-Markovnikoff	syn addition	Sometimes you might see BH <sub>3</sub> THF or B <sub>2</sub> H <sub>6</sub> used here: it's the same reagent in a slightly different form. The base (can be NaOH, KOH, identity unimportant) helps make H <sub>2</sub> O <sub>2</sub> more reactive. The reaction is <i>anti</i> - Markovnikoff because the H–B bond is polarized toward H (electronegativity of H = 2.2, B = 2.0) - the H adds to the carbon best able to stabilize positive charge (i.e. the most substituted one).		
Oxymercuration	$\begin{array}{c} \text{1) Hg(OAc)}_2 \\ \text{R} \xrightarrow{\text{I}} \text{R} \xrightarrow{\text{H}} 2) \\ \text{NaBH}_4 \end{array} \xrightarrow{\text{HO}} \begin{array}{c} \text{HO} \\ \text{R} \xrightarrow{\text{HO}} \text{H} \\ \text{R} \xrightarrow{\text{HO}} \text{R} \xrightarrow{\text{HO}} \\ \text{R} \xrightarrow{\text{HO}} \text{R} \xrightarrow{\text{HO}} \\ \text{R} \xrightarrow{\text{HO}} \text{R} \xrightarrow{\text{HO}} \\ \text{R} \xrightarrow{\text{HO}} \xrightarrow{\text{HO}} \\ \text{R} \xrightarrow{\text{HO}} \xrightarrow{\text{HO}} \\ \text{R} \xrightarrow{\text{HO}} \xrightarrow{\text{HO}} \xrightarrow{\text{HO}} \\ \text{R} \xrightarrow{\text{HO}} \xrightarrow{\text{HO}} \xrightarrow{\text{HO}} \\ \text{R} \xrightarrow{\text{HO}} \text$	Markovnikoff	syn + anti	This reaction goes through 3-membered "mercurinium" ion. The NaBH <sub>4</sub> step removes the mercury. While the addition is anti, the overall reaction is stereorandom because this step involves a carbon based free radical (usually not discussed). Alternatively, an alcohol used in place of water will produce an ether.		
Acid-catalyzed addition of H <sub>2</sub> (hydration)	$0 \qquad \begin{array}{c} R, - R \\ R \\ H \\ H_2 \\ H_$	Markovnikoff	syn + anti	Strong acid protonates the alkene, generating free carbocation. Watch out for possibility of rearrangements when a tertiary carbocation could be generated through a 1,2 shift. $HSO_4^-$ anion is not strongly nucleophilic, hence it does not add. Gives a mixture of syn and anti products due to the free carbocation.		
Addition of HX	$ \begin{array}{c} R_{I, -, R} \\ R^{H} \\ R^{H} \end{array} \stackrel{HCI}{\longrightarrow} \begin{array}{c} R \\ R^{H} \\ R^{H} \\ R $	Markovnikoff	syn + anti	HCI and HBr (as well as HI, not pictured) protonate the alkene to carbocation which can then be trapped by the halide anion. Gives	give a free a mixture of syn	and anti
Addition of HX		Markovnikoff	syn + anti	Br		
Bromination	$B_{r_2} \rightarrow B_{r_1} \rightarrow B_{r_1} \rightarrow B_{r_2} \rightarrow B_{r_1} \rightarrow B_{r$	N/A	anti addition	R R Bromonium ion mecha R H Br or H <sub>2</sub> O/ROH depending or	n solvent	
Halohydrin Formation	$\mathbf{R} \xrightarrow{\mathbf{H}} \mathbf{H} \xrightarrow{\mathbf{Br}_2} \begin{array}{c} \mathbf{HO} \\ \mathbf{R} \\ \mathbf{H}_2 \\ \mathbf{H}_2 \\ \mathbf{R} \\ \mathbf{R} \\ \mathbf{H} \\ H$	Markovnikoff	anti addition	The key detail in these reactions is solvent: water and alcohol solvents will form the halohydrin products (the ones containing the OH and Br). All other solvents (you might see CCI <sub>4</sub> , CHCI <sub>3</sub> , hexane, etc. ) provide the dibromide.		
Chlorination	$\begin{array}{c} R \\ R \\ \end{array} \xrightarrow{R} H \\ \end{array} \begin{array}{c} CI_2 \\ R \\ \end{array} \xrightarrow{R} \\ R \\ \end{array} \begin{array}{c} CI_1 \\ R \\ \end{array} \xrightarrow{R} \\ R \\ CI \\ CI \\ \end{array}$	N/A	anti addition	As with bromination, above. Although not depicted, use of water or alcohol as solvent will also lead to formation of the halohydrin product (also anti).		
Dihydroxylation	$\begin{array}{c} R_{2,\ldots,1},R \\ R \xrightarrow{OSO_4} \\ R \xrightarrow{H} \\ R \xrightarrow{OSO_4} \\ R \xrightarrow{H} \\ R \xrightarrow{R \xrightarrow{H} \\ R \xrightarrow{R \xrightarrow{H} \\ R R \xrightarrow{R \xrightarrow{\mathsf{$	N/A	syn addition	Osmium is a transition metal. The tools won't be given in this course to fully understand how this reaction works. Occasionally a second reagent like NaHSO <sub>3</sub> , H <sub>2</sub> S, or Na <sub>2</sub> S <sub>2</sub> O <sub>3</sub> is also given as a reactant in this reaction - minor detail, it's used to remove the osmium from the hydroxyl groups.		
Dihydroxylation	$\begin{array}{c} R, \dots, R \\ R \end{array} \xrightarrow{ KMnO_{4} } \begin{array}{c} HO \\ R, \dots, R \\ H \end{array} \xrightarrow{ Cold, dilute } \begin{array}{c} HO \\ R, \dots, R \\ H \end{array}$	N/A	syn addition	Keywords are "cold, dilute". <b>NOTE:</b> If "heat" or "acid" is mentioned in the conditions, the diol will be cleaved to provide carbonyl compounds (same reaction as ozonolysis with <b>oxidative workup</b> , below).		
Epoxidation		N/A	syn addition	$RCO_3H$ is a peroxyacid. A common peroxy acid for this reaction ( <i>m</i> -chloroperoxybenzoic acid). If $H_3O^+$ , heat is written afterward is opening of the epoxide to give the diol (anti-selective)		о о.он <i>m</i> -срва
Hydrogenation	$\begin{array}{c} R_{,,\ldots},R \\ R \xrightarrow{H_2} H \\ \end{array} \xrightarrow{H_2} \begin{array}{c} H_2 \\ Pd/C \\ R \xrightarrow{H} H \\ H \end{array}$	N/A	syn addition	The catalyst can vary - you might see Pt or Ni as well. All provid stereochemistry.	e the same produ	ct with the same
Radical addition of HBr	R H HBr H Br peroxides R R H (RO-OR) R H	Anti-Markovnikoff	syn + anti	Peroxides generate the Br• radical, which adds to the double bond in the way that will generate the most stable radical (i.e. the radical will go on to the most substituted carbon). This explains the selectivity for the anti-Markovnikoff product. It gives a mixture of syn and anti because it goes through a free radical process.		
Ozonolysis (Reductive work	$(p) \qquad \qquad$	+ 0≕ <mark>,</mark> R H		Reductive workup: Zinc (Zn), or dimethyl sulfide (DMS, $Me_2S$ ) of the aldehyde.	is a reducing age	nt. It reduces excess ozone, allowing for isolation
Ozonolysis (Oxidative Worku		+ 0=,R		Oxidative workup: Hydrogen peroxide is used to obtain the car Can also use KMnO <sub>4</sub> and acid	boxylic acid instea	ad of the aldehyde. Omissions, Mistakes, Suggestions?
Cyclopropanation	$\begin{array}{c} H_{1,1} \\ H_{1,2} \\$	N/A	syn addition	This reaction goes through addition of a <i>carbene</i> (actually, "carb the double bond. The reaction is stereospecific. Another set of conditions to provide a cyclopropane is <b>CHCI<sub>3</sub> wit</b> <b>base (NaOH)</b> , which makes the dichlorocyclopropane.		james@masterorganicchemistry.com This sheet copyright 2015, James A.
